When should one inline recursive functions?

Christian Chavez

January 23, 2015

Nico Reissmann, Magnus Jahre, and Christian Chavez are with the Norwegian University of Science and Technology (NTNU).

Abstract

Hello, here is some text without a meaning. This text should show what a printed text will look like at this place. If you read this text, you will get no information. Really? Is there no information? Is there a difference between this text and some nonsense like "Huardest gefburn"? Kjift – not at all! A blind text like this gives you information about the selected font, how the letters are written and an impression of the look. This text should contain all letters of the alphabet and it should be written in of the original language. There is no need for special content, but the length of words should match the language.

1 Introduction

Describe layout of paper. What does each section in turn discuss?

1.1 Problemsetting

Re-state the assignment: Inlining -¿ Easy, what is it, benefits/drawbacks. "This paper details the problems and benefits of inlining"
Introduce Jive in a few sentences, say that it's further introduced in section 2.

Inlining is a simple and straight-forward technique used in code compilation, where one replaces the call of a function with the body of said function. Its benefits include removal of function call overhead, and more importantly, unveiling of additional potential optimizations in the code. However, the drawback is potentially increased code size, and longer execution times for the compilation of the program.

The contribution of this paper is an inliner for the Jive compiler, and detailing the problems and benefits of inlining wrt. the Jive compiler. Jive is a new backend compiler using intermediate representation (IR), and an alternative to the control flow graph (CFG); the regionalized value-state dependency graph (RVSDG[1]).

Further details of this assignment can be found in Appendix A.

2 Background

2.1 The Regionalized Value-State Dependency Graph

- γ blocks/regions in the RVSDG are conditionals. The inputs of each γ block is the variables(/data) upon which the conditional depends, as well as the operation performed on these. A CNF may then be represented as several nested γ blocks, all the while retaining the properties of a demand-dependence graph.
- θ blocks/regions are the loop constructs.

  Need better explanation.

- λ blocks/regions are the functions. They retain the demand-dependency graph properties by implementing

  Ask Nico for help?

- ϕ blocks/regions are the ones describing mutually recursive environments. Inside a ϕ region, the RVSDG will have at least one λ region, and perhaps more. If there is more than one λ present, then the "mutually recursive binding group" situation which P. Jones and Marlow [4] describe when discussing how to inline recursive functions, is also present in the program flow represented by this RVSDG.

7.2 Inlining

W. Davidson and M. Holler [2] examine the proposition that the increased code-size of inlined code affects the execution time performance on demand-paged virtual memory machines. Using equations developed to the describe an inlined programs' execution time, they test this propositing through the use of a source-to-source subprogram inliner.

Cavazos and F.P. O'Boyle [1] uses a genetic algorithm in their auto-tuning heuristics to show how conjunctive normalform (CNF) can easily be used to decide if and when to inline a specific call site. They report between 17% and 37% execution time improvements without code explosion.

Serrano [5] implements an inliner in the Scheme programming language. He details an algorithm for which functions to inline, as well as an algorithm for how to inline reccursive functions and non-recursive functions.

Waterman's Ph.D. thesis [6] examines the use of techniques to adaptively decide which functions to inline.

E. Hank, W. Hwu, and R. Rau [3] introduces a new technique called *Region-Based Compilation*. And exhibits the benefits an aggressive compiler can have from inlining.

P. Jones and Marlow [4] explore a inlining approach for the Glasgow Haskell Compiler (GHC). The paper introduces a novel approach for deciding which mutually recursive functions can be (if any) safely inlined for optimization purposes.

A Project Description

Project Description: An Inliner for the Jive compiler

Nico Reissmann

December 12, 2014

Compilers have become an essential part of every modern computer system since their rise along with the emergence of machine-independent languages at the end of the 1950s. From the start, they not only had to translate between a high-level language and a specific architecture, but had to incorporate optimizations in order to improve code quality and be a par with human-produced assembly code. One such optimization performed by virtually every modern compiler is *inlining*. In principle, inlining is very simple: just replace a call to a function by an instance of its body. However, in practice careless inlining can easily result in extensive *work* and *code duplication*. An inliner must therefore decide carefully when and where to inline a function in order to achieve good performance without unnecessary code bloat.

The overall goal of this project is to implement and evaluate an inliner for the Jive compiler back-end. The project is split in a practical and an optional theoretical part. The practical part includes the following:

- Implementation of an inliner for the Jive compiler back-end. The inliner must be able to handle recursive functions and allow for the configuration of different heuristics to permit rapid exploration of the parameter space.
- An evaluation of the implemented inliner. A particular emphasis is given to different heuristics and their consequences for the resulting code in terms of work and code duplication.

The Jive compiler back-end uses a novel intermediate representation (IR) called the Regionalized Value State Dependence Graph (RVSDG). If time permits, the theoretical part of the project is going to clarify the consequences of using the RVSDG along with an inliner. It tries to answer the following research questions:

- What impact does the RVSDG have on the design of an inliner and the process of inlining?
- Does the RVSDG simplify/complicate the implementation of an inliner and the process of inlining compared to other commonly used IRs?

The outcome of this project is threefold:

1. A working implementation of an inliner in the Jive compiler back-end fulfilling the aforementioned criteria.
2. An evaluation of the implemented inliner.
3. A project report following the structure of a research paper.
